ABSTRACT

Dual action lethal containers, systems and methods and novel compositions and formulas which are used to kill mosquitoes and their larvae. Generally pyramid shaped containers can have combined interior larvicidal and adulticidal coatings above and below a side opening in the container. A removable inclined grate cap can also allow for mosquitoes to enter into the container. Inclined stacked walls inside the container form attractive surfaces for mosquitoes to breed. Water-holding containers, such as flower pots, water holding dishes used under plant pots, vases, bird baths, and fountains and storm water inlets, can be coated with novel larvicide and/or adulticide coatings. Small objects can be coated with larvicide or larvicide and adulticide combination, which can be dropped in water-holding containers which can leach out pesticide over time which prevents mosquitoes from breeding in the water-holding containers.

MOSQUITO CONTROL DEVICE USING DURABLE COATING-EMBEDDED PESTICIDES

CROSS REFERENCE TO RELATED APPLICATION

This application claims the benefit of priority to U.S. Provisional Application Ser. No. 61/777,766 filed Mar. 12, 2013, the disclosure of which is incorporated by reference in its entirety.

GOVERNMENT LICENSE RIGHTS

This invention was made with Government support under Dept. of Agriculture—Agricultural Research Service Agreement No.: 58-0208-3-001 (Durable Coating-Embedded Adulticide (CEA), Larvicide (CEL) and Durable Dual-Action Lethal Ovitrap (DDALO) for Management of Dengue Vector *Aedes albopictus* and Other Container-Breeding Mosquitoes). The government has certain rights in this invention.

FIELD OF INVENTION

This invention relates to killing mosquitoes, and in particular to lethal containers, apparatus, devices, systems, coatings, compositions, formulas, applications and methods of using pesticide coatings to kill adult mosquitoes and their larvae, and in particular to containers coated internally with coating-embedded pesticides designed to hold water, to attract mosquitoes, and kill adult mosquitoes and their larvae, which include specific shaped containers, and applications of using the coating-embedded larvicide to various objects such as tokens, marbles, pebbles, and the interior of various water-holding containers, such as flower pots, water-holding dishes used under plant pots, vases, bird baths, fountains, and other similar containers, and the like.

BACKGROUND AND PRIOR ART

Over the years, ovitrap type containers have been used and deployed to control mosquitoes. See for example, U.S. Pat. No. 5,983,557 to Perich et al.; U.S. Pat. No. 6,185,861 to Perich; and U.S. Pat. No. 6,389,740 to Perich et al.; and Zeichner, Brian C. "The lethal ovitrap: a response to the resurgence of dengue and chikungunya", U.S. Army Medical Journal, July-September 2011. These types of ovitraps have generally used a paper strip having insecticide that hangs within a cup filled with water up to a series of drain holes. The insecticide strip will hang into the water, with the intention of killing female mosquitoes as they land on the ovitrap to lay eggs. However, these types of Ovitrap have limitations due to the insecticide on the paper breaking down rapidly because of water contact, and also the trap is not designed to kill larvae.

For example, these traps have lacked the use of a timed release of insecticide, and the water ended up breaking down the insecticide to become ineffective or not killing fast enough to prevent egg laying because of insecticide resistance in the mosquito population. A study in Key West, Fla. that used thousands of ovitraps ended up producing mosquitoes from these water filled containers. Additionally, the ovitraps only used an adulticide, which was not effective in killing mosquito larvae.

Still furthermore, Mosquito ovitraps available in the market do not contain larvicide and only adulticide so if eggs are laid larvae can develop. The addition of larvicide would prevent that problem.

2

Thus, the need exists for solutions to the above problems with the prior art.

SUMMARY OF THE INVENTION

A primary objective of the present invention is to provide dual action lethal containers, apparatus, devices, systems, applications and methods, which are used to kill adult mosquitoes and their larvae.

A secondary objective of the present invention is to provide novel, long-lasting coatings, compositions and formulas that can be used to kill both adult mosquitoes and their larvae.

A third objective of the present invention is to provide mosquito control devices and methods of using and coating water-holding containers, such as but not limited to flower pots, water holding dishes used under plant pots, vases, bird baths, and fountains coated internally with coating containing a mosquito larvicide.

A fourth objective of the present invention is to provide mosquito control devices and methods of coating pebbles, stones, marbles and other types of objects coated with coating-embedded larvicide which can be added to water-holding containers.

A fifth objective of the present invention is to provide mosquito control devices and methods of imbedding objects with durable coatings which releases the larvicide over time so that its action can be prolonged over the duration of a fully season.

Long lasting insecticidal coatings used in the invention can prevent quick degradation of insecticidal activity as occurs when insecticides are applied directly to surfaces of lethal ovitraps.

Use of slow release coatings encapsulates most insecticide so that pesticide exposure by humans is minimized when treated surfaces are accidentally contacted.

Use of different active ingredients for elimination of adults and larvae can delay development of pesticide resistance in mosquito populations and provide more efficient control of disease vectors.

Containment of insecticides within an ovitrap can minimize environmental contamination, non-target exposure and chances of accidental insecticide poisoning to humans and animals.

Improvements over the prior art.

The use of long-lasting insecticidal coating provides long-lasting control, as opposed to direct application of insecticides to internal surfaces of lethal ovitraps. The invention has the addition of larvicide to lethal ovitraps. A synergist can be added to the long-lasting coating to overcome insecticide resistance in mosquito populations. The coating not only can protect the insecticidal active ingredient, but also synergists from degradation over time. Additionally, a combination of both an adulticide and a larvicide with a different mode of action in a single coating could allow for easier manufacturing.

Marketing Novelty.

The dual action ovitrap can be sold both in the retail market, for use by homeowners who need to eliminate mosquitoes from their property, and professional market, for use by mosquito control districts, pest control operators, the armed forces, humanitarian institutions and others involved in the control of mosquitoes in different situations.

The long-lasting insecticide coatings can be marketed for other uses where insect control is desired. Such coating could be used in external building walls, internal walls, and any other surfaces where mosquitoes and other pestiferous insects may rest and congregate.

The insecticidal coatings can have colors incorporated that are attractive to mosquitoes. This dual action lethal ovitrap would be useful for control of mosquitoes that vector dengue, west Nile virus, yellow fever, and other pathogens.

Embedding the insecticides in coatings within lethal ovitrap can protect the active ingredient and/or synergist from degradation by the water in the ovitrap, and results in slow release of the active ingredient over time to kill mosquitoes. If the mosquitoes lay eggs before they die, a larvicide also embedded in the coating, is protected from degradation, and slowly releases over time to kill any larvae that hatch from the mosquito eggs. The dual action of the ovitrap assures that the device will not produce mosquitoes as a result of degradation of the active ingredients.

Further objects and advantages of this invention will be apparent from the following detailed description of the presently preferred embodiments, which are illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 is a perspective left front side of a first embodiment dual action ovitrap container.

FIG. 2 is a front view of the dual action ovitrap container of FIG. 1.

FIG. 3 is a top view of the dual action ovitrap container of FIG. 1.

FIG. 4 is a side cross-sectional view of the dual action ovitrap container of FIG. 2 along arrow 4X.

FIG. 5A is a right side view of another dual action ovitrap container.

FIG. 5B is a cross-sectional view of the container of FIG. 5A along arrow 5B.

FIG. 6 is a front view of the dual action ovitrap container of FIG. 5 along arrow 6X.

FIG. 7 is a left side view of the dual action ovitrap container of FIG. 5.

FIG. 8 is a top view of the dual action ovitrap container of FIG. 5 along arrow 8X.

FIG. 9 shows another embodiment of using the novel coatings with a flower pot.

FIG. 10 shows another embodiment of using the novel coatings with water-holding dishes used under a plant pot.

FIG. 11 shows another embodiment of using the novel coatings with a water-holding vase.

FIG. 12 shows another embodiment of using the novel coatings with a water-holding bird bath.

FIG. 13 shows another embodiment of using the novel coatings with a water-holding fountain.

FIG. 14 shows another embodiment of using the novel coatings with a small objects in a water-holding storm-water inlet.

FIG. 15 shows another embodiment of using the novel coatings with small objects that can be used with another water-holding area.

FIG. 16 shows another embodiment of using the novel coatings on wood surfaces, such as stalls and fences and walls.

FIG. 17 is a graph of mosquito larval mortality after 0-week aging with the average live mosquitoes on the vertical axis versus exposure time on the horizontal axis.

FIG. 18 is a graph of mosquito larval mortality after 20-week aging with the average live mosquitoes on the vertical axis versus exposure time on the horizontal axis.

FIG. 19 is a graph of percent of mosquito eggs on the vertical axis versus cavity size on the horizontal axis.

FIG. 20 shows a bar graph of results of a two-way choice test for mosquito females placed in a small-cage with containers with CEA (0.7% permethrin) vs. control, both using unchlorinated water, with number of dead mosquitoes and percentage of eggs found in each treatment on the vertical axis.

FIG. 21 shows a bar graph of results of a two-way choice test for mosquito females placed in a small-cage with containers with CEA (0.7% permethrin) vs. control, both with oak-leaf infusion water, with number of dead mosquitoes and percentage of eggs found in each treatment on the vertical axis.

FIG. 22 shows a bar graph of a two-way ovitrap choice test with *Aedes albopictus*, with percentage of mosquitoes on the vertical axis versus the location where they were found.

FIG. 23 shows percent adult mosquito emergence on the vertical axis versus coatings in which the larvicide pyriproxyfen was embedded at different rates.

FIG. 24 shows percent adult mosquito emergence on the vertical axis versus two coatings in which the larvicide pyriproxyfen was embedded and applied to containers which were washed with different volumes of water.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Before explaining the disclosed embodiments of the present invention in detail it is to be understood that the invention is not limited in its applications to the details of the particular arrangements shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

A list of the components will now be described.

- 100 First embodiment container
- 110 narrow cap top on container
- 112 grate with openings
- 120 raised ribs
- 121 internal concave ribs
- 122 upper end of container
- 126 lower curved side edges
- 128 bottom of container
- 130 hook
- 140 sideway protruding raised opening
- 200 First embodiment container
- 210 narrow cap top on container
- 212 grate with openings
- 220 raised ribs
- 221 inner rib surfaces
- 222 upper end of container
- 226 lower curved side edges
- 228 bottom of container
- 230 hook
- 240 sideway protruding raised opening
- 300 flower pot
- 310 internal surface of pot
- 400 plant pot with water dish
- 420 dish
- 425 internal surface of dish
- 430 pot
- 500 vase
- 510 internal surface of vase
- 600 bird bath
- 610 internal surface of bowl
- 700 fountain
- 710 internal surface of fountain
- 800 coated objects for a storm water inlet
- 810 interior surface of storm water inlet

5

900 coated objects for another water holding container
 910 interior surface of another container
 1000 small mosquito control coated objects
 1100 wood stalls and fences and walls and boxes

FIG. 1 is a perspective left front side of a first embodiment dual action ovitrap container 100. FIG. 2 is a front view of the dual action ovitrap container 100 of FIG. 1. FIG. 3 is a top view of the dual action ovitrap container 100 of FIG. 1. FIG. 4 is a side cross-sectional view of the dual action ovitrap container 100 of FIG. 2 along arrow 4X.

Referring to FIGS. 1-4, container 100 can have a modified pyramid shape with rounded sides. Insects such as mosquitoes can enter inside the container through grate 112, and side raised opening 140. The container 100 can include a raised side opening 140 so that water inside the container is maintained to be no higher than the bottom of the side opening 140. Any water inside the container 100 can run out of side opening 140.

On the top of the container 100 can be an attachable cap such as a snap-on cap 110. Alternatively the cap 110 can be threadably attached to the upper portion of the container 100. A grate 112 within openings therethrough can be oriented at an inclined angle and be used to obstruct objects larger than insects, such as but not limited to leaves, branches, hands, fingers and the like, from entering container 100.

The narrow opening can create dead-air, high humidity conditions that mosquitoes prefer as oviposition and resting sites. A narrow opening can also prevent excessive rain from entering and rinsing larvicide from the interior of the ovitrap. The narrow opening also can prevent dilution of the larvicide and adulticide active ingredients which can slowly escape from the coatings in order to control mosquitoes.

The inclined grate 112 opening increases the attractiveness of the trap for the mosquito. A horizontal oriented grate would not be as effective an attractant opening as an inclined grate. The inclined grate 112 also more closely replicates an opening in a tree which is usually not horizontal and the tree opening which can hold water is the most attractive hatching condition for attracting mosquitoes into the container 100.

A built on hook 130, such as a loop, can be used to hang the container 100 in an elevated position such as but not limited to hanging the container 100 from a branch, under a tree, and the like. The novel ovitrap 100 can be deployed on a surface through bottom 128 or hanging by hook 130 from a support, as opposed to single-action ovitraps that need to be placed on a completely horizontal surface. The hook 130 offers many more opportunities for placement of ovitraps in locations that are more attractive to mosquitoes and protected from animal activities, as well as in conditions that prevent disturbances by children.

Raised ribs 120 on the container 100 form concave curved stacked sections 121 inside the container 100. The stacked concave interior surfaces 121 allow for an easier landing surface for the mosquitoes to land on and hatch. The ribs 120 and interior surfaces 121 are slightly inclined so that when water evaporates and goes down, each rib section 120 and corresponding interior surface 121 have a section above and below the water level.

The ribs 120 and interior surfaces 121 have the effect of limiting the wind turbulence that can enter inside of the container 100 through the side opening 140 and grate 112. Incoming wind can cause a Venturi effect inside the container 100. The inside stacked concave rib sections 121 can reduce the Venturi effect and any turbulence inside the container 100. This is very important since Mosquitoes prefer to lay eggs when there is less or no wind.

6

The bottom 128 of the container 100 can be flat to allow for the container stability to stand on its' own on a ground or raised flat surface, with lower side curved edges 126.

The inside walls of the container can be coated with a single coating having both larvicide and adulticide described in reference to the tables below. The double coating can be coated on interior walls and the floor both below and above the water line formed from side opening 140.

The container 100 can be formed from molded plastic material such as those used to form water bottles and the like, with a rougher interior surface.

The plastic container 100 can be pretreated in order to make the interior surface coatings rough and not too smooth, in order to provide cavities of approximately 150 to approximately 500 μm wide.

Mosquitoes prefer to deposit eggs in indentations on the surface of containers. Laboratory testing for desired cavity sizes was done at the University of Florida, Gainesville, Fla. in the summer of 2013, where the inventors modified wood surfaces (using popsicle sticks), and glued plastic mesh on top of the sticks. Six different sizes of mesh were tested, each being placed in a cup of water, which were placed in a lab cage where mosquitoes were present. The holes of the mesh became the sides of the cavities and the wood being the bottom of the cavities. The materials were left untreated, and testing and observations was completed to determine which mesh size was most desirable for the female mosquitoes to lay their eggs. Laboratory testing determined the highest results of killed mosquitoes occurred with mesh cavity having dimensions of approximately 250 μm wide. A range of approximately 150 to approximately 500 μm wide was also determined to cover desirable mesh size cavities. The term approximately can include $\pm 10\%$. The textured internal surfaces with formed cavities demonstrate that optimum resting and oviposition can be obtained by modifying the coatings accordingly.

The interior walls surfaces of the containers 100 can be roughened into having textured surfaces with cavities by at least three different processes.

One process can include using a plastic or material that inherently has a rough surface. The plastic can be formed from molds that form selected cavity sizes on the interior surfaces of the plastic container.

Another process can include re-treating the interior surfaces of a container, such as plastic with a separate textured material coating that artificially forms a roughened surface. For example, a paintable primer, or a sprayable primer, and the like, can be used. The textured material coatings can be selected in order to create the selected, cavity sizes based on applying those material coatings to the surfaces of the container.

Mosquitoes can enter either by the top or the side entry into the container (which can have a partial bottle configuration). The mosquitoes have a choice of vertical and horizontal surfaces to rest, all of which are coated with insecticidal coating. Any coating and/or primer can be applied inside the container by various techniques such as but not limited to inserting a spray nozzle in the bottle and spraying around to cover 360° internally below a selected level.

A still another process can include adding additional grains such as but not limited to sand, acrylics, into the insecticide coating, which can then be coated to the interior surfaces of the container which forms a roughened surface, having the selected cavity sizes. Similarly, techniques to spray inside the container can include but are not limited to having any coating and/or primer can be applied by inserting a spray nozzle into

7

the opening(s) of the container and spraying around to cover 360° internally below a selected level.

The outside of the container **100** can have different colors. The exterior of container can be darkened to black, brown, and other dark colors that replicate a tree type structure. For example, a dark color attracts mosquitoes.

The cap **110** can have a different color such as red that causes contrast with the dark color of the rest of the container **100**, which would replicate surfaces of the tree having wet and dry areas. Mosquitoes associate red and black to ideal tree surface locations.

The side opening **140** and the grate opening also appear to replicate a tree surface along with the coloring of the container surface, which are attractive to mosquitoes.

The inside of the container **100** can include a separate mosquito attractant either or both embedded into the coating or loose inside the container **100**. The attractant can include but it not limited to broken leaves, artificial and natural scents, contained or not in cloth, paper, or mesh bag similar to a teabag that can replicate moist wet areas that are normally attractive to mosquitoes.

The object of the interior surface of the container with or without the attractant is to form an attractant environment and not a repellent environment for mosquitoes.

Table 1 lists examples of adulticide and larvicidal coating ingredients that can be used in the interior coatings of the container **100** along with a range for each components and preferred percentage for combined adultacidal and larvacidal coating.

TABLE 1

Main Ingredients	Choice Ingredients	Preferred Range	Preferred Exemplary Amount
Choice of Coating		83.0-99.9989%	98.59%
Acrylic paint			
Oil based paint

	Chlorpyrifos (organophosphate)	0.2-5.0%	0.5%
	Propoxur (carbamate)	0.2-5.0%	0.5%
	Diazinon (organophosphate)	0.2-5.0%	1.0%
Choice of Synergist:		0-10.0%	0.7%
	Piperonyl Butoxide	0-10.0%	0.7%
	MGK-264	0-10.0%	1.4%
	Etofenprox	0-5.0%	0.7%
	Pyrethrins	0-5.0%	0.7%

Table 3 lists the main components along with a range for each components and preferred percentage for larvacidal coating.

TABLE 3

Main Ingredients	Choice Ingredients	Preferred Range	Preferred Exemplary Amount
Coating (choice of one)		88.0-99.9999%	99.82%
Acrylic paint			
Oil based paint			
Plastic polymer			
Choice of Larvicidal Active Ingredients:		0.0001-2%	0.01%
	<i>Bacillus thuringiensis israelensis</i>	0.0001-2%	0.01%
	Methoprene	0.0001-2%	0.01%
	Pyroproxifen	0.0001-2%	0.01%
	Spinosad	0.0001-2%	0.01%
Choice of 1-3 Synergists:		0-10.0%	0.7%
	Piperonyl Butoxide	0-10.0%	0.7%
	MGK-264	0-10.0%	1.4%
	Etofenprox	0-5.0%	0.7%
	Pyrethrins	0-5.0%	0.7%

The interior surface coatings can include those described and used in related U.S. patent application Ser. No. 13/866, 656 to Koehler et al. which is assigned to the same assignee as that of the subject invention, and which is incorporated by reference in its' entirety.

FIG. 5A is a right side view of another dual action ovitrap container **200**. FIG. 5B is a cross-sectional view of the container of FIG. 5A along arrow 5B. FIG. 6 is a front view of the dual action ovitrap container **200** of FIG. 5 along arrow 6X. FIG. 7 is a left side view of the dual action ovitrap container **200** of FIG. 5. FIG. 8 is a top view of the dual action ovitrap container **200** of FIG. 5 along arrow 8X.

Referring to FIGS. 5A-8, part numbers **210**, **212**, **220**, **221**, **222**, **226**, **228**, **230**, **240** correspond and function to similar part numbers **110**, **112**, **120**, **121**, **122**, **126**, **128**, **130** and **140** in the previous embodiment. In these figures, the bottom of the container **200** can have a length between the back and front of approximately 5 inches and a width between the left side and right side of approximately 4¾ inches, and a height between the bottom **228** and the upper end of the container

200 being approximately $4\frac{1}{2}$ inches from the bottom 228 of the container 200, with the upper end having a length of approximately $2\frac{1}{8}$ inches and a width of approximately $2\frac{3}{4}$ inches. The parallel raised ribs 220 can be spaced apart from each other by approximately $\frac{1}{2}$ inch and each rib can be approximately $\frac{1}{2}$ inch thick, and can extend outward from the sides of the container 200 by approximately $\frac{3}{8}$ of an inch. Each of the ribs 220 can be angled downward from the front of the container to the rear of the container. At the bottom 228 of the container 200, the lowest rib can start approximately $1\frac{1}{4}$ inches from the front of the container 200 and angle downward to be approximately 1 inch from the rear of the container 200.

The ribs 220 and interior surfaces 221 have the effect of limiting the wind turbulence that can enter inside of the container 200 through the side opening 240 and grate 212. Incoming wind can cause a Venturi effect inside the container 200. The inside stacked concave rib sections 221 can reduce the Venturi effect and any turbulence inside the container 200. This is very important since Mosquitoes prefer to lay eggs when there is less or no wind.

The novel ovitrap internal incline plane rib surfaces offer both horizontal and vertical surfaces for female mosquitoes to oviposit and rest. This configuration makes these surfaces available to oviposition and resting regardless of the level of the water in the ovitrap. All of these surfaces can be coated with the coating-embedded larvicides and adulticides.

The inclined grate 212 can have a generally oval shape with a width of approximately $2\frac{3}{4}$ inches. The sideways protruding opening 240 can be generally oval shape with a height of approximately $1\frac{1}{8}$ inches and a width of approximately $\frac{7}{8}$ inch. Other dimensions are shown in the figures.

The coatings described above, and all their applications with the containers 100, 200 can be used with other water holding containers, and objects.

FIG. 9 shows another embodiment of using the novel coatings with a flower pot 300. The internal surface 310 can be coated with coatings containing a mosquito larvicide coatings.

FIG. 10 shows another embodiment of using the novel coatings with a water holding dishes 420 used under a plant pot 430. The internal surface 425 of the dish 420 can be coated with coatings containing a mosquito larvicide coatings.

FIG. 11 shows another embodiment of using the novel coatings with a water holding vase 500. The internal surface 510 of the vase 500 can be coated with coatings containing a mosquito larvicide coatings.

FIG. 12 shows another embodiment of using the novel coatings with a water holding bird bath 600. The internal surface 610 of the bath bowl can be coated with coatings containing a mosquito larvicide coatings.

FIG. 13 shows another embodiment of using the novel coatings with a water holding fountain 700. The internal surface 710 of the fountain can be coated with coatings containing a mosquito larvicide coatings.

Additional mosquito control objects 1000 can be coated with larvicide such as but not limited to pebbles, stones, marbles and other types of objects coated with coating-embedded larvicide. These small coated objects can be placed in water holding containers such as but not limited to using untreated containers previously described or other types of containers so that the larvicide can leach out over time.

Additionally, the interior coated water holding containers can also have the small coated objects 100 dropped inside the containers.

FIG. 14 shows another embodiment of using the novel coatings with a small coated objects 1000 in a water holding

storm water inlet 800. Alternatively internal surface areas 810 in the storm water inlet can also be coated with coatings containing mosquito larvicide coatings. The small coated objects can also be dropped into standing water in storm water inlets and the like so as to prevent those areas from becoming larvae breeding grounds. Also any other type of standing water can use the coated small objects dropped into the standing water.

FIG. 15 shows another embodiment of using the novel coatings with a small coated objects 1000 in another water holding container 900 such as an aquarium. Alternatively, internal surface areas 910 can also be coated with coatings containing mosquito larvicide coatings.

FIG. 16 shows another embodiment of using the novel coatings on wood surfaces 1100, such as wooden stalls for horses and fences and walls and boxes, and the like. Other surfaces that can become damp and wet, such as but not limited to other wood surfaces and the like, can also be treated with the coatings.

FIGS. 17-24 show the results of testing using the containers and different coatings of the first two embodiments of the invention described above for killing mosquitoes.

FIG. 17 is a graph of mosquito larval mortality over 0-week aging with amount of mosquitoes on the vertical axis versus exposure time on the horizontal axis.

FIG. 18 is a graph of mosquito larval mortality over 20-week aging on the vertical axis versus exposure time on the horizontal axis.

FIG. 19 is a graph of percent of mosquito eggs on the vertical axis versus cavity size on the horizontal axis.

FIG. 20 shows a bar graph of results of a two-way choice test for mosquito females placed in a small-cage with containers with CEA (0.7% permethrin) vs. control, both using unchlorinated water, with number of dead mosquitoes and percentage of eggs found in each treatment on the vertical axis.

FIG. 21 shows a bar graph of results of a two-way choice test for mosquito females placed in a small-cage with containers with CEA (0.7% permethrin) vs. control, both with oak-leaf infusion water, with number of dead mosquitoes and percentage of eggs found in each treatment on the vertical axis.

FIG. 22 shows a bar graph of a two-way ovitrap choice test with *Aedes albopictus*, with percentage of mosquitoes on the vertical axis versus the location where they were found.

FIG. 23 shows percent adult mosquito emergence on the vertical axis versus coatings in which the larvicide pyriproxyfen was embedded at different rates. FIG. 24 shows percent adult mosquito emergence on the vertical axis versus two coatings in which the larvicide pyriproxyfen was embedded and applied to containers which were washed with different volumes of water.

Referring to FIGS. 17-18, the placement of the larvicide pyriproxyfen in a coating does not prevent its action in preventing mosquito emergence, either with new material or material that had been aged for 20 weeks. In water that is in contact with the coating-embedded larvicide, or larvicide applied directly to the container without coating, mosquito larvae start to die as they reach the pupal stage. This shows that the coating does not interfere with the larvicide action. By embedding the larvicide pyriproxyfen in a coating, the mosquito killing action is protected from degradation for more than 20 weeks.

Referring to FIG. 19, mosquitoes (*Aedes aegyptii* and *Aedes albopictus*) preferred to lay eggs in cavities of 250 μ m size, whereas smaller and larger cavities were not as preferred, and very large cavities (2000 μ m) were even less

11

preferred. This figure shows that a certain texture to the coating or container walls can make it a preferred oviposition site.

Referring to FIGS. 20-22, female mosquitoes were placed in cages where they had a choice of 2 containers filled with water to stimulate oviposition, one container with a coating-embedded adulticide (CEA) containing the adulticide permethrin, and the other container containing no insecticide. Reference to FIG. 20, pure water was used, whereas reference to FIG. 21, the water was mixed with oak-leaf infusion. In both tests, higher numbers of dead mosquito females were found in the adulticide-containing water, whereas greater number of eggs were found in containers with no insecticide. The presence of leaf infusion did not prevent the insecticidal action of the coating-embedded adulticide.

Referring to FIG. 22, adult female mosquitoes were found dead mostly in the container coated with coating-embedded adulticide, whereas few mosquitoes were found dead in the water-only control or the cage floor. This shows that once the adults contact the coating-embedded adulticide, they normally do not leave the container and die. Few mosquitoes that are able to fly away from the container with the coating-embedded adulticide also die later.

Referring to FIG. 23, three different coating were used to embed the larvicide pyriproxyfen at 3 different rates. Coatings were applied to plastic containers that were filled with water, before mosquito larvae were transferred to these containers. The addition of pyriproxyfen to different coatings produced similar results (no emergence of mosquitoes even at low pyriproxyfen content) while in the water standard, mosquito emergence was only inhibited at the high pyriproxyfen level. This shows that the different coatings can protect the action of pyriproxyfen.

Several different formulae (polycrylic, Polyurethane and Latex paint) have been tested as coatings for the larvicide. All coatings performed well in preventing adult emergence from larvae added to water-holding containers coated internally with the coating-embedded larvicide even with 0.0001% of the active ingredient in the coating. Water treated with 0.01% rate is considered potable by the World Health Organization (WHO).

Referring to FIG. 24, two of the coating tested previously (refer to FIG. 23) were also tested for durability under high volume washing to see if they could stand under heavy rains. The coatings applied to plastic containers were subject to continuous washing with tap water for total volumes equivalent to 5x, 20x, and 50x the container volumes. After wards the containers were refilled with fresh water and mosquito larvae were added to the water. Adult emergence from the larvae was only observed in containers with coatings that contained no embedded larvicide. The larvicide embedded in both coatings prevented the emergence of adults, even when the coating was washed with 50x volume of water. Coatings prevent larvicide washing off, with up to 50 times the volume of water as contained in the ovitrap. Most larvicides are applied to water and disappear when containers are emptied and re filled either naturally by rain action or by other means. The coating constantly treats new water put in containers with enough larvicide to preserve the mosquito-killing action. Both polycrylic and polyurethane protect the action of pyriproxyfen larvicide when containers coated with these materials are subjected to washing. This shows that coating-embedded larvicide can survive extensive rain-water rinsing.

The addition of larvicide kills any larvae that can emerge from eggs that females are able to lay before dying from exposure to adulticide in the lethal ovitrap. Field deployment of single-action lethal ovitrap allowed development of larvae which can lead to actual increase in the mosquito population.

12

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it has presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

We claim:

1. A dual action container for killing insects and their larvae, comprising:

- a generally pyramid shaped housing having a closed bottom and closed sidewalls with and a narrow upper end with an inclined substantially narrower open top with a grate thereon;
- a single side extended opening in the housing substantially at least midway between the closed bottom and the open top; and
- an adulticidal coating layer on an inner surface of the housing;
- a larvicidal coating layer on an inner surface of the housing, wherein the adulticidal coating layer and the larvicidal coating layer kills both adult insects and their larvae over time.

2. The dual action container of claim 1, wherein the adulticidal coating includes: permethrin.

3. The dual action container of claim 1, wherein the larvicidal coating includes: pyriproxyfen.

4. The dual action container of claim 1, wherein the insects include mosquitoes.

5. The dual action container of claim 1, wherein at least one of the adulticidal coating and the larvicidal coating includes a mixture for a long lasting insecticide that does not break down.

6. The dual action container of claim 1, wherein the container includes:

- side walls having stacked raised ribs with interior surfaces of the side walls have raised ledge sections.

7. The dual action container of claim 6, wherein the stacked ribs include parallel inclined stacked ribs.

- 8. The dual action container of claim 1, further comprising: a snap-on cap for the inclined open top of the container.

- 9. The dual action container of claim 1, further comprising: a side hook for hanging the container in an elevated position.

10. The dual action container of claim 1, further comprising:

- cavities formed in the inner coating layer that attract mosquitoes.

11. The dual action container of claim 10, wherein the cavities each have a range of approximately 150 to approximately 500 μm wide.

12. The dual action container of claim 1, further comprising:

- a separate mosquito attractant, selected from the group consisting of broken leaves, artificial and natural scents, contained or not in cloth, paper, or mesh bag similar to a teabag that can replicate moist wet areas that are normally attractive to mosquitoes.

13. The dual action container of claim 12, wherein the separate mosquito attractant is embedded in the coating layer.

14. The dual action container of claim 12, wherein the separate mosquito attractant is loose inside the container.

15. A method for coating interior surfaces of water-holding containers, comprising the steps of:

- providing a water-holding container having a generally pyramid shaped housing having a closed bottom and

13

closed sidewalls with and a narrow upper end with an inclined substantially narrower open top with a grate thereon

providing a single side extended opening in the housing substantially at least midway between the closed bottom 5 and the open top; and

coating interior surfaces of the water-holding containers with a coatings having a mosquito killing coating.

16. The method of claim **15**, further comprising the step of: forming cavities on the inner surfaces that attract mosqui- 10 toes.

17. The method of claim **16**, wherein the method of forming the cavities includes the step of forming each cavity to have a range of approximately 150 to approximately 500 μm wide. 15
